

Economics 101A (Lecture 15)

Stefano DellaVigna

October 19, 2006

Outline

1. Returns to Scale II
2. Two-step Cost Minimization
3. Cost Minimization: Example

1 Returns to Scale II

- Nicholson, Ch. 7, pp. 190–193 [OLD: Ch. 11, pp. 275–278]

- Increase of all inputs: $f(t\mathbf{z})$ with t scalar, $t > 1$

- How much does output increase?

- Decreasing returns to scale: for all \mathbf{z} and $t > 1$,

$$f(t\mathbf{z}) < tf(\mathbf{z})$$

- Constant returns to scale: for all \mathbf{z} and $t > 1$,

$$f(t\mathbf{z}) = tf(\mathbf{z})$$

- Increasing returns to scale: for all \mathbf{z} and $t > 1$,

$$f(t\mathbf{z}) > tf(\mathbf{z})$$

- Example: $y = f(K, L) = AK^\alpha L^\beta$
- Marginal product of labor: $f'_L =$
- Decreasing marginal product of labor: $f''_L =$
- $MRTS =$
- Convex isoquant?
- Returns to scale: $f(tK, tL) = A(tK)^\alpha (tL)^\beta = t^{\alpha+\beta} AK^\alpha L^\beta = t^{\alpha+\beta} f(K, L)$

2 Two-step Cost minimization

- Nicholson, pp. 212–220 [OLD, Ch. 12 , pp. 298–307]
- Objective of firm: Produce output that generates maximal profit.
- Decompose problem in two:
 - Given production level y , choose cost-minimizing combinations of inputs
 - Choose optimal level of y .
- *First step.* Cost-Minimizing choice of inputs

- Two-input case: Labor, Capital
- Input prices:
 - Wage w is price of L
 - Interest rate r is rental price of capital K
- Expenditure on inputs: $wL + rK$
- Firm objective function:

$$\begin{aligned} \min_{L, K} & wL + rK \\ \text{s.t.} & f(L, K) \geq y \end{aligned}$$

- Equality in constraint holds if:
 1. $w > 0, r > 0$;
 2. f strictly increasing in at least L or K .
- Counterexample if ass. 1 is not satisfied
- Counterexample if ass. 2 is not satisfied

- Compare with expenditure minimization for consumers

- First order conditions:

$$w - \lambda f'_L = 0$$

and

$$r - \lambda f'_K = 0$$

- Rewrite as

$$\frac{f'_L(L^*, K^*)}{f'_K(L^*, K^*)} = \frac{w}{r}$$

- MRTS (slope of isoquant) equals ratio of input prices

- Graphical interpretation

- Derived demand for inputs:

$$- L = L^*(w, r, y)$$

$$- K = K^*(w, r, y)$$

- Value function at optimum is **cost function**:

$$c(w, r, y) = wL^*(r, w, y) + rK^*(r, w, y)$$

- *Second step.* Given cost function, choose optimal quantity of y as well
- Price of output is p .
- Firm's objective:

$$\max py - c(w, r, y)$$

- First order condition:

$$p - c'_y(w, r, y) = 0$$

- Price equals marginal cost – very important!

- Second order condition:

$$-c''_{y,y}(w, r, y^*) < 0$$

- For maximum, need increasing marginal cost curve.

3 Cost Minimization: Example

- Continue example above: $y = f(L, K) = AK^\alpha L^\beta$
- Cost minimization:

$$\begin{aligned} \min \quad & wL + rK \\ \text{s.t.} \quad & AK^\alpha L^\beta = y \end{aligned}$$

- Solutions:
 - Optimal amount of labor:

$$L^*(r, w, y) = \left(\frac{y}{A}\right)^{\frac{1}{\alpha+\beta}} \left(\frac{w\alpha}{r\beta}\right)^{-\frac{\alpha}{\alpha+\beta}}$$

- Optimal amount of capital:

$$\begin{aligned} K^*(r, w, y) &= \frac{w\alpha}{r\beta} \left(\frac{y}{A}\right)^{\frac{1}{\alpha+\beta}} \left(\frac{w\alpha}{r\beta}\right)^{-\frac{\alpha}{\alpha+\beta}} = \\ &= \left(\frac{y}{A}\right)^{\frac{1}{\alpha+\beta}} \left(\frac{w\alpha}{r\beta}\right)^{\frac{\beta}{\alpha+\beta}} \end{aligned}$$

- Check various comparative statics:
 - $\partial L^* / \partial A < 0$ (technological progress and unemployment)
 - $\partial L^* / \partial y > 0$ (more workers needed to produce more output)
 - $\partial L^* / \partial w < 0, \partial L^* / \partial r > 0$ (substitute away from more expensive inputs)

- Parallel comparative statics for K^*

- Cost function

$$\begin{aligned}
 c(w, r, y) &= wL^*(r, w, y) + rK^*(r, w, y) = \\
 &= \left(\frac{y}{A}\right)^{\frac{1}{\alpha+\beta}} \left[w \left(\frac{w\alpha}{r\beta}\right)^{-\frac{\alpha}{\alpha+\beta}} + r \left(\frac{w\alpha}{r\beta}\right)^{\frac{\beta}{\alpha+\beta}} \right]
 \end{aligned}$$

- Define $B := w \left(\frac{w\alpha}{r\beta}\right)^{-\frac{\alpha}{\alpha+\beta}} + r \left(\frac{w\alpha}{r\beta}\right)^{\frac{\beta}{\alpha+\beta}}$

- Cost-minimizing output choice:

$$\max py - B \left(\frac{y}{A}\right)^{\frac{1}{\alpha+\beta}}$$

- First order condition:

$$p - \frac{1}{\alpha + \beta} \frac{B}{A} \left(\frac{y}{A} \right)^{\frac{1-(\alpha+\beta)}{\alpha+\beta}} = 0$$

- Second order condition:

$$-\frac{1}{\alpha + \beta} \frac{1 - (\alpha + \beta)}{\alpha + \beta} \frac{B}{A^2} \left(\frac{y}{A} \right)^{\frac{1-2(\alpha+\beta)}{\alpha+\beta}}$$

- When is the second order condition satisfied?

- Solution:

- $\alpha + \beta = 1$ (CRS):

- * S.o.c. equal to 0

- * Solution depends on p

- * For $p > \frac{1}{\alpha+\beta} \frac{B}{A}$, produce $y^* \rightarrow \infty$

- * For $p = \frac{1}{\alpha+\beta} \frac{B}{A}$, produce any $y^* \in [0, \infty)$

- * For $p < \frac{1}{\alpha+\beta} \frac{B}{A}$, produce $y^* = 0$

– $\alpha + \beta > 1$ (IRS):

* S.o.c. positive

* Solution of f.o.c. is a minimum!

* Solution is $y^* \rightarrow \infty$.

* Keep increasing production since higher production is associated with higher returns

– $\alpha + \beta < 1$ (DRS):

* s.o.c. negative. OK!

* Solution of f.o.c. is an interior optimum

* This is the only "well-behaved" case under perfect competition

* Here can define a supply function
